# Machine learning I, supervised learning: logistic regression

# General classification problem

- $\mathcal{X} = \mathbb{R}^d$
- $ightharpoonup \mathcal{Y} = \{-1, 1\} \text{ or } \mathcal{Y} = \{0, 1\}.$
- $I(y,z) = 1_{y\neq z}$  ("0-1" loss)
- $ightharpoonup F = \mathcal{Y}^{\mathcal{X}}$

### Problem

Optimizing on  $F = \mathcal{Y}^{\mathcal{X}}$  is equivalent to optimizing in the set of subsets of  $\mathcal{X}$ .

We cannot differentiate on this hypothesis space and it is not clear how to regularize.

# Using scikit

#### Exercice 1:

Use scikit to perform a logistic regression on the **digits** dataset. template : **logistic\_regression/logistic\_regression\_digits.py** 

### Subsets

### Exercice 2: Combinatorial problem

If we wanted to try all mappings in  $\mathcal{Y}^{\mathcal{X}}$ , if  $|\mathcal{X}|=n$ , how many mappings would there be?

### Real-valued function

Instead of an application in  $\mathcal{Y}^\mathcal{X}$  , we will learn  $g:\mathcal{X}\to\mathbb{R}$  and define  $f(x)=\mathrm{sign}(g(x))$  with

$$sign(x) = \begin{cases} 1 \text{ if } x \ge 0 \\ -1 \text{ if } x < 0 \end{cases}$$

### Risk

The risk (generalization error) of  $f = sign \circ g$  writes :

$$R(g) = P(\operatorname{sign}(g(x)) \neq y)$$

$$= E \left[ 1_{\operatorname{sign}(g(x)) \neq y} \right]$$

$$= E \left[ 1_{yg(x) < 0} \right]$$
(1)

### Several solutions

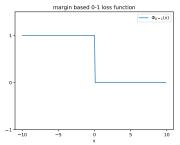

There might be many optimal maps g, i.e : such that  $\operatorname{sign}(g(x)) = f^*(x)$  for all x. (Here,  $f^*(x)$  is the Bayes predictor, which is the optimal predictor : it minimizes the generalization error (risque réel))

# Margin based 0-1 loss function $\Phi_{0-1}$

$$R(g) = E \left[ 1_{\operatorname{sign}(g(x)) \neq y} \right]$$

$$= E \left[ 1_{yg(x) < 0} \right]$$

$$= E \left[ \Phi_{0-1}(yg(x)) \right]$$
(2)

# Empirical risk minimization

The corresponding empirical risk writes:

$$\frac{1}{n} \sum_{i=1}^{n} \Phi_{0-1}(y_i g(x_i)) \tag{3}$$

Issue with this objective function?

- non-convex
- not continuous

# Convex surrogate

Key idea : replace  $\Phi_{0-1}$  by another function  $\Phi$  that is easier to optimize (convexity) but still represents the correctness of the classification.

Natural question : but does minimizing the  $\Phi\text{-risk}$  lead to a good "0-1" loss prediction? Answering this question requires an advanced study.

# Most common convex surrogates

#### **Définition**

Logistic loss

$$\Phi(u) = \log(1 + e^{-u}) \tag{4}$$

With linear predictors  $(g(x_i) = \langle \theta, x_i \rangle)$ , this loss will lead to **logistic regression** (which is classification despite its name).

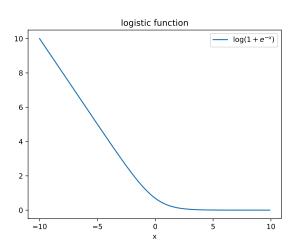

# Most common convex surrogates

If  $\mathcal{Y} = \{0,1\}$ ,  $\hat{y}$  is the prediction and y is the correct label, then we sometimes write :

$$I(\hat{y}, y) = y \log(1 + e^{-\hat{y}}) + (1 - y) \log(1 + e^{\hat{y}})$$
 (5)

(cross entropy loss)

# Logistic function

### Most common convex surrogates

#### Définition

Hinge loss

$$\Phi(u) = \max(1 - u, 0) \tag{6}$$

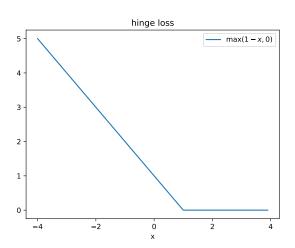

With linear predictors, this loss will lead to **Support vector** machines.

#### **Définition**

Squared hinge loss

$$\Phi(u) = (\max(1 - u, 0))^2 \tag{7}$$

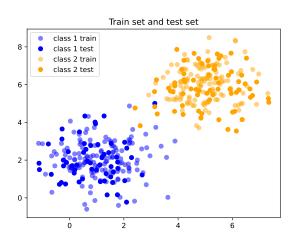

# Hinge loss

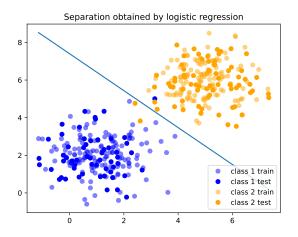

# Logistic regression

- $ightharpoonup g(x) = \langle x, \theta \rangle = x^T \theta.$
- $f(x) = sign(\langle x^T \theta \rangle)$
- ▶ It can be seen as "linear regression applied to classification".

# Application on a toy dataset

# Application on a toy dataset

# Logistic regression

In this section we use the setting  $\mathcal{Y} = \{0, 1\}$ .

► prediction : 
$$\hat{y} = x^T \theta$$

$$I(\hat{y}, y) = y \log(1 + e^{-\hat{y}}) + (1 - y) \log(1 + e^{\hat{y}})$$
 (8)

(cross entropy loss)

# Logistic regression estimator

If I is the logistic loss, it is defined as

$$\hat{\theta}_{logit} = \operatorname*{arg\,min}_{\theta \in \mathbb{R}^d} \frac{1}{n} \sum_{i=1}^n I(x_i^T \theta, y_i)$$

### Logistic regression

We can show that the logistic loss is stricly convex in  $\theta$ :

$$\theta \mapsto y \log(1 + e^{-x^T \theta}) + (1 - y) \log(1 + e^{x^T \theta})$$
 (9)

This means that if we manage to fing  $\theta$  that cancels the **gradient** of the empirical risk,  $\theta$  is a global minimizer.

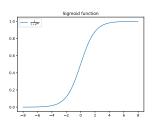

# Sigmoid

#### **Définition**

Sigmoid function

$$\sigma: \mathbb{R} \to \mathbb{R}$$
.

$$\sigma(x) = \frac{1}{1 + e^{-x}} \tag{10}$$

### No closed-form solution

Since the loss is convex, to minimize it is sufficient to look for the cancellation of the gradient. However, the corresponding equation has no closed-form solution.

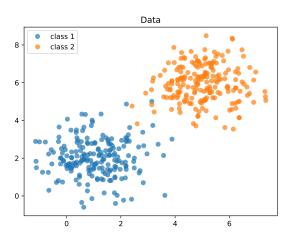

We thus need to use iterative algorithms (Gradient descent, Newton's method)

# Practical usage of logistic regression

In practice, it is common practice to :

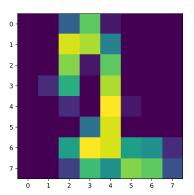

- ► regularize the logistic loss to avoid overfitting, for instance with a *L*2 penalty (as in ridge regression)
- use feature maps and classify with  $\phi(x)$  instead of x.

### Application to a simple 2D dataset.

Application to the digits dataset.
