# Machine learning I, supervised learning: risks

#### Notion of risks

- ► We are ready to introduce an important notion that is specific to machine learning and optimization : the risk
- there are several types of risks and several denominations for each.
- ▶ this denomination "risk" might seem counter-intuitive at first, as there is no notion of danger involved. However, this is a classical term in optimization and ML.

# Setting

#### We consider

- lacktriangle an input space  $\mathcal{X}$  (e.g.  $\mathcal{X}=\mathbb{R}^d$ )
- ightharpoonup an output space  ${\cal Y}$ .

In supervised learning, we predict outputs  $y \in \mathcal{Y}$  from inputs  $x \in \mathcal{X}$ .

- ▶ classification : discrete  $\mathcal{Y}$ , e.g.  $\mathcal{Y} = \{0,1\}$ ,  $\mathcal{Y} = \{-1,1\}$ ,  $\mathcal{Y} = \{0,1,2\}$ .
- ▶ regression : continuous  $\mathcal{Y}$ , e.g.  $\mathcal{Y} = \mathbb{R}$ ,  $\mathcal{Y} = [a, b]$ .

The couples (x, y) are called **samples** and are considered to be sampled from a joint random variable (X, Y).

# Supervised learning

- Assumption : there exists a joint probability law  $\rho$ , such that  $(X,Y)\sim \rho$ . However,  $\rho$  is unknown.
- ▶ Hence there exists a map  $f: \mathcal{X} \mapsto \mathcal{Y}$ , such that Y = f(X).
- f is most of the time non deterministic.

**Supervised Learning** : from a finite dataset of samples, produce an estimate  $\tilde{f}$  of f.

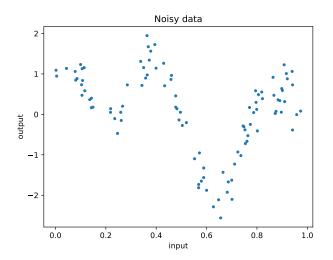

Figure – Finite dataset in 1 dimension

#### Loss functions

A **loss function** *I* is a map that measures the discrepancy between to elements of a set.

$$I: \left\{ \begin{array}{l} \mathcal{Y} \times \mathcal{Y} \to \mathbb{R}_+ \\ (y, y') \mapsto I(y, y') \end{array} \right.$$

We use it in order to evaluate the quality of our prediction  $\tilde{f}(x)$ , that should be close to the label y that corresponds to x.

#### Common loss functions

▶ "0-1" loss (for classification.)

$$I(y,z) = 1_{y \neq z} \tag{1}$$

squared loss (for regression)

$$ightharpoonup \mathcal{Y} = \mathbb{R}.$$

$$I(y,z) = (y-z)^2$$
 (2)

$$\mathcal{Y} = \mathbb{R}^d$$

$$I(y,z) = ||y - z||_2^2 \tag{3}$$

▶ absolute loss (for regression).  $\mathcal{Y} = \mathbb{R}$ .

$$\mathcal{V} = \mathbb{R}$$
.

$$I(y,z) = |y-z| \tag{4}$$

$$\mathcal{V} = \mathbb{R}^d$$

$$I(y,z) = ||y - z||_1 \tag{5}$$

## Prerequisite: expected value

Let Z be a real random variable. If it is correctty defined, the expected value is

▶ for a discrete random variable (that can take the values  $\{z_i, i \in \mathbb{N}\}$ .

$$E[Z] = \sum_{i=1}^{+\infty} z_i P(Z = z_i)$$
 (6)

for a continuous random variable

$$E[Z] = \int_{-\infty}^{+\infty} zp(z)dz \tag{7}$$

p(z) is the density of probability of Z, assumed to exist.

## Expected values

Expected value of an unbiased dice game :

$$E[Z] = \frac{1}{6}[1+2+3+4+5+6] = 3.5$$
 (8)

Exepected value of a cheated dice game :

$$E[Z] = \frac{1}{100}(1+2+3+4) + \frac{48}{100}(5+6) = 5.38$$
 (9)

### Risks

- lackbox We call "estimator" a map  $\mathcal{X}\mapsto\mathcal{Y}$
- We note  $D_n = \{(x_1, y_1), \dots, (x_n, y_n), i \in [1, n]\}$  the dataset. From  $D_n$ , we want to estimate f.

To measure the quality of some estimator g, we consider the **risks**:

Risk / generalization error ("risque réel" in french)

$$R(g) = E_{(X,Y) \sim \rho}[I(Y,g(X))] \tag{10}$$

Empirical risk ("risque empirique" in french)

$$R_n(g) = \frac{1}{n} \sum_{i=1}^n I(y_i, g(x_i))$$
 (11)

Both risks depend on the loss function /!

## Risks

Risk / generalization error :

$$R(g) = E_{(X,Y)\sim\rho}[I(Y,g(X))]$$
 (12)

**Problem**: we cannot compute R(g)!

### Risks

Risk / generalization error :

$$R(g) = E_{(X,Y)\sim\rho}[I(Y,g(X))]$$
 (13)

**Problem**: we cannot compute R(g)!

We **only** have access to the empirical risk.

$$R_n(g) = \frac{1}{n} \sum_{i=1}^n I(y_i, g(x_i))$$
 (14)

given the finite dataset  $D_n = \{(x_1, y_1), ..., (x_n, y_n), i \in [1, n]\}.$ 

# Law of total probability

If for instance  $\Omega = A \cup B \cup C$  and A, B, C are mutually exclusive and collectively exhaustive (système complet d'événements), then

$$P(X) = P(X \cap A) + P(X \cap B) + P(X \cap C) \tag{15}$$

https://en.wikipedia.org/wiki/Law\_of\_total\_probability  $\Omega$  is the sample space.

# Conditional probabilities

$$P(A \cap B) = P(A|B)P(B) \tag{16}$$

# Generalization of the penalty shootout example

We consider the following random variable (X, Y).

- $\mathcal{X} = \{0,1\}, \ \mathcal{Y} = \{0,1\}.$
- ►  $X \sim B(\frac{1}{2})$ ,

$$Y = \begin{cases} B(p) & \text{if } X = 1 \\ B(q) & \text{if } X = 0 \end{cases}$$

With B(p) a Bernoulli law with parameter p.

#### We consider 3 estimators:

$$f_1 = \begin{cases} 1 & \text{if } x = 1 \\ 0 & \text{if } x = 0 \end{cases}$$

$$f_2 = \begin{cases} 0 \text{ if } x = 1\\ 1 \text{ if } x = 0 \end{cases}$$

$$\forall x \in \mathcal{X}, f_3(x) = 1 \tag{17}$$

#### Exercice 1:

We observe the following dataset :

$$D_4 = \{(0,1), (0,0), (0,0), (1,0)\}$$

Compute the **empirical risks**  $R_4(f_1)$ ,  $R_4(f_2)$ ,  $R_4(f_3)$  with the "0-1" loss.

$$R_n(f) = \frac{1}{n} \sum_{i=1}^n I(y_i, f(x_i))$$

### Real risks

Exercice 2: Now, compute the real risks  $R(f_1)$ ,  $R(f_2)$ ,  $R(f_3)$ .

$$R(f) = E[I(Y, f(X))]$$
(18)

$$R(f_{1}) = E[I(Y, f(X))]$$

$$= 1 \times P(I(Y, f(X)) = 1) + 0 \times P(I(Y, f(X)) = 0)$$

$$= 1 \times P(Y \neq f(X)) + 0 \times P(Y = f(X))$$

$$= P(Y \neq f(X))$$
(19)

# Random variables or deterministic quantities

- ▶  $R_4(f)$  (empirical risk) **depends** on  $D_4$ . If we sample another dataset,  $R_4(f)$  is likely to change, it is a **random variable**.
- ightharpoonup R(f) (generalization error) is **deterministic**, given the joint law of (X, Y).

# Optimization problem : empirical risk minimization

- ▶ The smaller the generalization error R(g) is, the better g is.
- ▶ The situation is more tricky for  $R_n(g)$ : it is not obvious that as estimator that has a very small empirical risk  $R_n(g)$  has a small generalization error R(g)! This is the problem of overfitting.

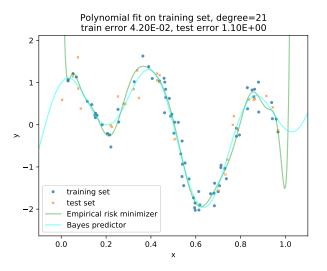

Figure – Overfitting : the green estimator has a small empirical risk, but it a large generalization.

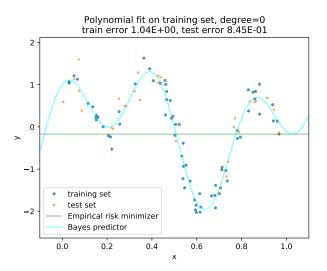

Figure – Very simple estimator

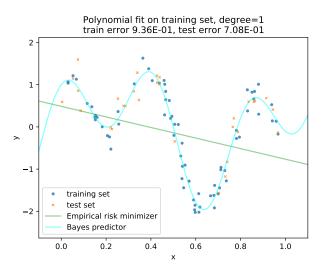

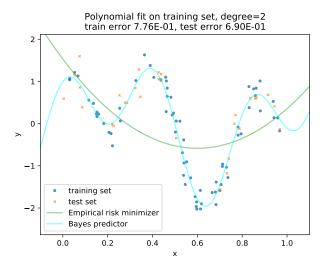

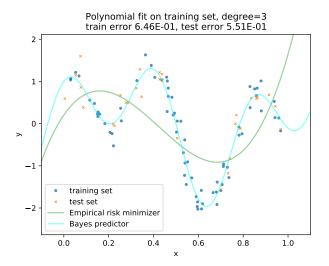

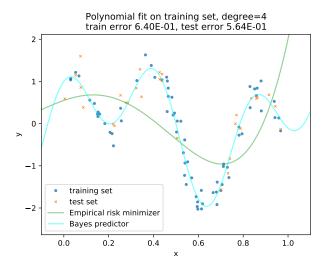

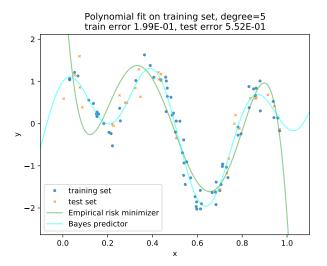

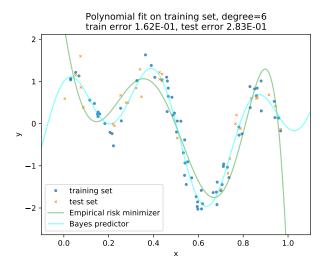

Figure – Very simple estimator

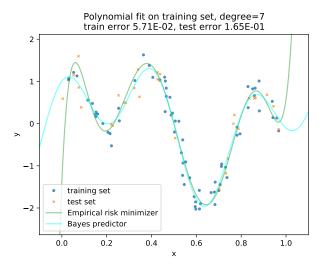

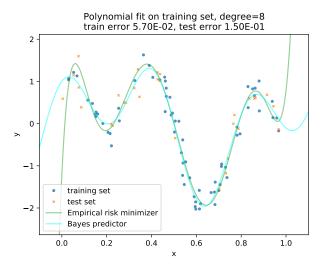

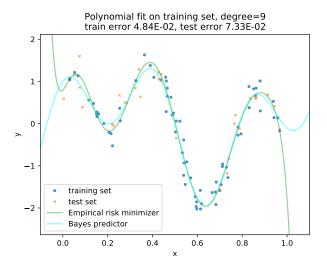

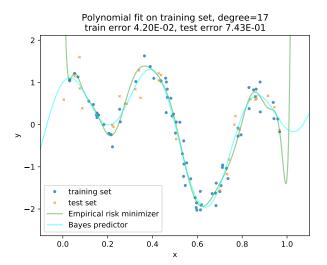

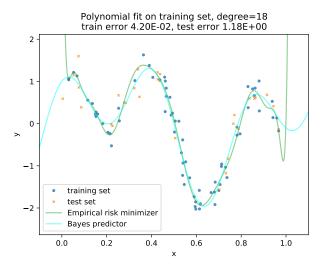

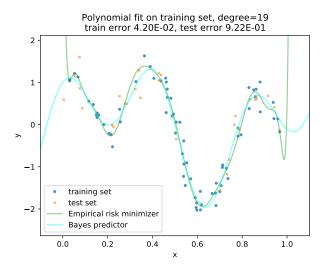

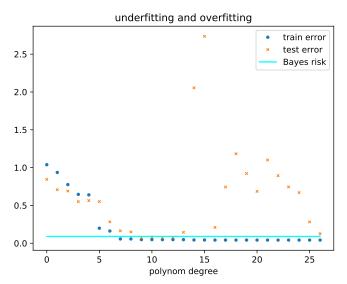

#### Randomness

If the data were deterministic (Y = f(X) is determinisic), there would be no overfitting!

Randomness might come from several sources, such as :

- measurement errors
- ▶ hidden variables (not represented in X)

### Optimization problem : empirical risk minimization

**Empirical risk minimization (ERM)**: finding the estimator  $f_n$  that minimizes the empirical risk  $R_n$ .

This raises important questions :

- ▶ 1) does  $f_n$  have a good generalization error  $R(f_n)$ ?
- ▶ 2) how can we have guarantees on the generalization error  $R(f_n)$ ?
- $\triangleright$  3) how can we find the empirical risk minimizer  $f_n$ ?
- $\triangleright$  4) is it even interesting to strictly minimize  $R_n$ ?

#### Generalization error

**Question 1)** Does  $f_n$  have a good generalization error  $R(f_n)$ ? This will depend on :

- ▶ the number of samples *n*
- ▶ the shape of f (the map such that Y = f(X)), in particular on its **regularity**
- $\blacktriangleright$  the distribution  $\rho$
- the dimensions of the input space and of the output space.
- $\triangleright$  the space of functions where  $f_n$  is taken from.

#### Statistical bounds

**Question 2)** How can we have guarantees on the generalization error  $R(f_n)$ ?

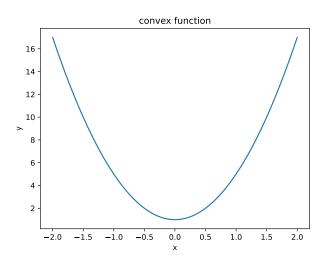

By making assumptions on the problem (learning is impossible without making assumptions), for instance assumptions on  $\rho$ .

### Optimization

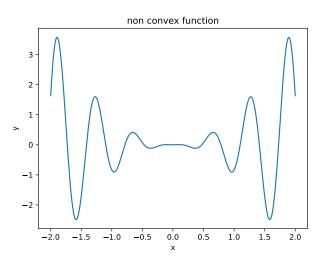

**Question 3)** how can we find the empirical risk minimizer  $f_n$ ? By using an optimization algorithm or by solving the minimization in closed-form.

### Convex functions

Convex functions are easier to minimize.

### Non convex functions

#### What is convex here?

In this context, the convexity that is involved is the dependence of  $R_n$  in g. More precisely, for instance if g depends on  $\theta \in \mathbb{R}^d$ , e.g.  $g(x) = \langle \theta, x \rangle$ , the convexity is that of

$$\theta \mapsto R_n(\theta) \tag{20}$$

Example (ordinary least squares) :

$$R_n(\theta) = \frac{1}{n} \sum_{i=1}^n (\langle \theta, x_i \rangle - y_i)^2$$
 (21)

with  $x_i \in \mathbb{R}^d$ ,  $y_i \in \mathbb{R}$ .

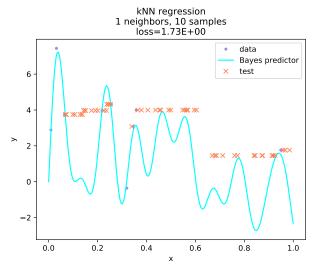

### Optimization error

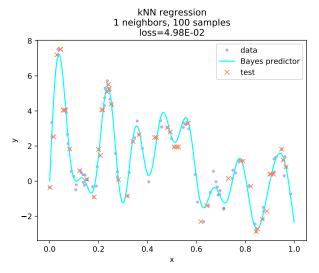

Question 4) is it even interesting to strictly minimize  $R_n$ ? Most of the time it is **not**, as we are interested in R, not in  $R_n$ , so we should not try to go to machine precision in the minimization of a quantity that is itsself an approximation! This is linked to the **estimation error** (advanced concept) that is often of order  $\mathcal{O}(1/\sqrt{n})$ .

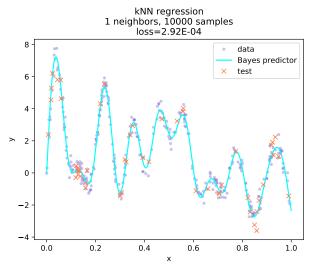

### Nearest neighbors algorithms

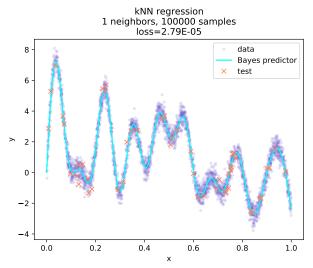

Not all supervised learning methods consist in Empirical risk minimization (ERM).

For instance the nearest neighbors algorithm is not an ERM.

## Bayes risk

Notion of bayes risk on the penalty shootout example.
